HOW DOES DISABILITY AFFECT TIME USE?

Study period: 1992 to 2010

Results:

- The results show that the time use for different populations is significantly different. For example, disabled people spend more time on personal care and screen time.

- There is evidence that the differences in time use among the disabled and non-disabled populations are becoming less dissimilar in terms of disability rights and programs. Yet, it is considered necessary to advance educational outcomes and well-being, particularly in areas of life that are sensitive to the effects of disability.

Conclusion:

- The results suggest that the policy must be one that contributes to the time use for disabled people. It is important to note that the differences in time use between disabled and non-disabled people are still significantly different in time allocated to paid work and education.

- The analysis suggests that public policy must be one that contributes to the time use for disabled people. It is important to note that the differences in time use between disabled and non-disabled people are still significantly different in terms of paid work and education.
